Embeddings in Natural Language Processing

Theory and Advances in Vector Representations of Meaning

Synthesis Lectures on Human Language Technologies

Editor

Graeme Hirst, University of Toronto

Synthesis Lectures on Human Language Technologies is edited by Graeme Hirst of the University of Toronto. The series consists of 50- to 150-page monographs on topics relating to natural language processing, computational linguistics, information retrieval, and spoken language understanding. Emphasis is on important new techniques, on new applications, and on topics that combine two or more HLT subfields.

SYNTHESIS LECTURES ON HUMAN LANGUAGE TECHNOLOGIES #47

ABSTRACT

Embeddings have undoubtedly been one of the most influential research areas in Natural Language Processing (NLP). Encoding information into a low-dimensional vector representation, which is easily integrable in modern machine learning models, has played a central role in the development of NLP. Embedding techniques initially focused on words, but the attention soon started to shift to other forms: from graph structures, such as knowledge bases, to other types of textual content, such as sentences and documents.

This book provides a high-level synthesis of the main embedding techniques in NLP, in the broad sense. The book starts by explaining conventional word vector space models and word embeddings (e.g., Word2Vec and GloVe) and then moves to other types of embeddings, such as word sense, sentence and document, and graph embeddings. The book also provides an overview of recent developments in contextualized representations (e.g., ELMo and BERT) and explains their potential in NLP.

Throughout the book, the reader can find both essential information for understanding a certain topic from scratch and a broad overview of the most successful techniques developed in the literature.

Preface

Semantic representation is one of the oldest areas of research in Natural Language Processing (NLP). This area lies at the core of language understanding and looks at ways to express meaning in a machine-interpretable form. Among different types of representation, vectors have always been a popular choice, owing to their simple geometrical intuition and versatility. In fact, vector representations (more recently, *embeddings*) have played a crucial role in improving the generalization ability of various NLP systems.

In the early 2010s, the field of semantic representation was dominated by word embeddings. One reason behind this success was that embeddings proved perfect complements for neural NLP models, which were getting increasing attention around those years. It did not take long for the research attention to be expanded to other areas of representation learning (e.g., graphs, sentences, senses), pushing the boundaries in those areas. More recently, a new branch has emerged, namely contextualized embeddings, in which representations and downstream NLP systems have become even more tied together. Contextualized models have proven effective not only in a wide range of NLP tasks but also in knowledge transfer across different languages.

This book presents an overview of the field of vector representation. As a significant extension and update of a survey article we had on the topic [Camacho-Collados and Pilehvar, 2018], this book reflects the subsequent development of the field, particularly for contextualized representations. Moreover, while the survey mainly focused on word-level embeddings, the book also discusses other types of embeddings that are commonly used in NLP, such as graph and sentence embeddings. Last but not least, this book was written with a different style and purpose, as our aim was to make it more accessible to a wider audience.

INTENDED READERSHIP

This book should be of interest to all AI researchers who work with natural language, especially those who are interested in semantics. Our goal is to introduce the topic of semantic representation to those who are new to the area and to provide those who are already familiar with the area with a broader perspective and a quick overview of recent developments and the state of the art in various branches. The book synthesizes the diverse literature on semantic representations and provides a high-level introduction to major semantic embedding models.

We note that in our overview of various techniques, we provide details only to the depth that is necessary to sketch the general shape of the field and provide a hint on how the research problem was approached. In these cases, we also provide relevant references to allow the reader

xvi PREFACE

to further investigate specific sub-areas. We hope this book can bring fresh researchers and practitioners up to speed on the recent developments in the field, while pointing out open problems and areas for further exploration.

COVERAGE AND OUTLINE

The book is split into nine chapters. The first two chapters provide basic concepts that can be helpful in understanding the remainder of the book. Chapters 3 to 7 are the core of this book, which discusses different types of embeddings. While there is some connection between these chapters, we tried to make them as self-contained and independent as possible. Chapter 8 discusses some of the implications of the common representation models, while Chapter 9 provides concluding remarks and future research prospects. In the following, we describe each individual chapter in more detail.

- In Chapter 1, we start with a brief introduction on why semantic representation is an
 important topic in NLP and discuss its evolution path. We also explain the basics of Vector
 Space Models.
- 2. In Chapter 2, we provide some **background knowledge** on the fundamentals of NLP and machine learning applied to language problems. Then, we briefly describe some of the main knowledge resources that are commonly used in lexical semantics.
- 3. Chapter 3 discusses **word representations**, starting from a brief overview of conventional count-based models and continuing with the more recent predictive embeddings. We also describe some of the techniques for specializing embeddings, which serve to produce knowledge-enhanced and cross-lingual word embeddings, and common evaluation methods for word representations.
- 4. Chapter 4 covers various techniques for embedding structural knowledge resources, in particular semantic **graphs**. We will overview major recent methods for embedding graph nodes and edges and conclude with their applications and evaluation.
- 5. In Chapter 5, we focus on the representation of individual meanings of words, i.e., **word senses**. Two classes of sense representations (unsupervised and knowledge-based) are discussed, followed by evaluation techniques for each type of representation.
- 6. Chapter 6 is about the recent paradigm of **contextualized embeddings**. We first explain the need for such embeddings and then describe the most popular models and their connection to language models. The chapter also covers some of the efforts to explain and analyze the effectiveness of contextualized models.
- 7. Chapter 7 goes beyond the level of words, and describes how **sentences and documents** can be encoded into vectorial representations. We cover some of the widely used supervised

- and unsupervised techniques and discuss the applications and evaluation methods for these representations. Given the book's main focus on word-level representation, this chapter provides partial coverage but also pointers for further reading.
- 8. Chapter 8 explains some of the **ethical issues and inherent biases** in vector representations (and, in particular, word embeddings), which recently have been a topic of concern. The chapter also covers proposals for debiasing word embeddings.
- 9. Finally, in Chapter 9 we present the concluding remarks and open research challenges.

We note that given its massive success, there has been a surge of interest in representation learning, resulting in rapid progress over the past few years, essentially making the state-of-the-art representation technique a moving target. Therefore, it is impossible to keep track of all the recent developments in the field; instead, we try to focus on some of the more established techniques and general concepts. In fact, during the writing of the book, the field of contextualized representation had changed so much that, upon the completion of the first draft, we had to go back to the corresponding chapter and significantly extend it with newer content. Nevertheless, as we mentioned, we tried to focus on the more general concepts and ideas that are relevant for understanding rather than individual systems that may change over time.

Finally, we would like to thank our editors, reviewers, colleagues, and all others who provided us with valuable feedback for improving the book. Also, we would like to thank our families for their patient support during the writing of this book.

Mohammad Taher Pilehvar and Jose Camacho-Collados November 2020
